Problem: 1

1)
$$T(n) = 3T(n/2) + n^2$$
.

here.

a bk

3 22.

Sothio is 18.8 p20, soil fall under.

3a-case.

$$T(n) = \Theta(n^2 \log^{\circ} n)$$
$$= \Theta(n^2).$$

4 22

condition in 2, now we have to check P, condition, to p=0

3)
$$T(n) = T(n)a) + n^2$$

 $\alpha = 1, b = 2, K = 2, P = 0$

This falls in 3a.

$$T(n) = \Theta(n^2 \log^2 n)$$
$$= \Theta(n^2).$$

(4) $T(n) = 2^n T(n) + n^n$ —) in master theorem cannot be applied, as the form say $aT(n|b) + \Theta(n^K \log^p n)$ so we cannot apply master theorem.

$$2=2$$
.

Condution $2(a)$.

 $T(n)=\Theta\left(n^{\log\log^{2}\log^{2}(n)}\right)$
 $=\Theta\left(n\log^{2}n\right)$
 $=\Theta\left(n\log^{2}n\right)$.

7)
$$T(n) = 2T(n/s) + n/\log n$$
.

we can re-write the following Equation in the below form.

 $2T(n/s) + n\log^{-1} n$.

 $2 = 2, b = 2, K = 1, P = -1$
 $2 = 2'$

So ibs

 $2(b)$
 $T(n) = \Theta(n\log\log n)$
 $= O(n\log\log n)$

8)
$$\forall (n) = 27(n)u) + no.51$$

Sq a=2b=4 K=0.51 p=0.

2 < 40.51

3a -> coope.

10)
$$T(n) = 6T(n/3) + n^2$$

$$Q = 6, b = 3, k = 9, P = \pm$$

$$6 < 3^2$$

$$3a \rightarrow case based on . compansiou$$

$$T(n) = \Theta(n^k \log^p n)$$

$$= \Theta(n^2 \log^n n)$$

$$= \Theta(n^2 \log^n n)$$

this also cannot solve using master theorm.

as the format does not match with

It's in condition 3 a.

$$= \Theta(n^2).$$

a=4, b=2, k=0, p=± Usince there is no, k-value in the Equation

$$= \Theta(n^2)$$

$$T(n) = \sqrt{2} T(n|2) + \log n$$
 $a = \sqrt{2} b = 2 K = 0 P = 1$
 $\sqrt{2} > 2^{\circ}$
 $1 - \cos e$,

 $T(n) = \Theta(n^{\log 6a}) = \Theta(n^{\log 2^{\sqrt{2}}})$
 $= \Theta(\sqrt{n})$

15)

$$T(n) = 2T(n|2) + \sqrt{n}$$

$$a = 2, b = 2, K = 1/2, P = 0$$

$$272^{1/2} \quad T(n) = \Theta(n^{\log_2 2})$$

$$= \Theta(n)$$

Data structures are classified as either linear or non-linear. A data structure is said to be linear if its elements from a sequence, or in other words, a linear list.

There are two basic ways of representing such Linear Structures in memory.

to one way is to have two linear relationship between the sequential memory locations.

Tuese linear structures are called arrays and. description to the tradition

The other way is to have the linear relationship between the elements represented by means of pointers or Links. Thieretinean structures are called Linked lists

The operations one normally performs on any linear structure whether it be an array or a linked list,

include the following

- a) Traversal processing each element in the list
 - b) search. finding the location of the Element with a given value or the record with a given key.
 - c) Insertion: Adding a new element to the list
- d) deletion: Removing an Element from the list
- e) Sorting: Arranging two lists into a single list.

The particular linear structure that one chooses for a given Situation depends on the relative frequency with which one performs these different operations ou que structure.

* Since arrays are usually easy to traverse, search and port they are frequently used to store relatively permanent collections of data.

On the other hand, if the size of the structure and the data the array may not be as useful a structure as the linked

Linear Array

de linear array is a list of a finite number of homogeneous data Elements (1 e data Elements of the same type) Such that:

- a) The elements of the array are referenced respectively by an index set consisting of consecutive numbers.
- b) The elements of the array are stored respectively in Successive memory locations.

The number n of elements is called the length or size

of the array.

if not explicitly stated, we will assume the index set consists of the integers 1,2,.., n.

* In general, the length or the number of data elements of the array can be obtained from the index set by tua formula.

Length = UB-LB+I.

where

UB is the largest index, called the upper bound, & LB is the smallest Index, colled the lower bound of the array.

Dote the Length = UB when LB = I

The elements of our array A may be denoted by the subscript notation

A,, A2, A3, -.., An.

(2)

or by the bracket notation (used in C).

. [U]A ..., [S]A, [S]A, [LI]A

we will usually use the subscript notation or the bracket notation.

Regardless of the notation, the number K in A[K] is called a se subscript or an Index and A[K] is called a subscripted variable -

Note: that subscripto allow any element of A to be referenced by its relative position in A.

Let DATA be a 6- Element linear array of integers such that 251 = [1] ATAC P\$4 = [6] ATAC 03 = [4] ATAC DATA[4] = [1] ATAC DATA [6] = [6] = 156.

Sometimes we will denote such an array by Simply DATA: 247,56,429, 135,87, 156. markind

The array DATA is frequently pictured as

DATA	
1 247	DATA
2 56	247 56 429 135 87 156
4 135	
6 156	(6)
(a)	

```
E11:-
```

on automobile company uses an array AUTO to record the number of automobiles sold each year from 1932 through to 1984.

Rather than beginning the Index set with I, it is more useful to begin the index set with 1932 so that

AUTO[K] = number of automobilier solid in the year K

Then LB=1932 is the lower bound and UB=1984 is the upper bound of AUTO

Length = UB-LB+1 = 1984-1932+1 = 55.

Jud is AUTO,

```

Defining Arrays in C+/

# include < stdlo.h7

main ()

int a[i0]; 1/1

for (int i = 0; i<10; i++)

a[i]=i;

print aray(a);

par void print array (int a[])

for (int i = 0; i<10; i++).

Print f ("value in the array ".d\n", a[i]);

}
```

statement I defines on array of integers of the size 10, which means you can store 10 integers.

* when we define due array, due size should be known

Subscripts are used to refer the Elements of the array where o is considered to be due lowest subscript always and the highest Subscript is (Size-I),

which is q in this case.

we can refer to any element as a [o], a [t], a [t], ---

* Each programming language has its own rules for declaring exportes.

Each such declaration must give, implicitly or Explicitly, three items of information.

- 1) the name of the array.
- 3) the data type of the ourant
- 3) the index set of the array.

float DATA [6];

(Suppose data in a 6- Element linear array containing real values. C-Language declares such an array as follows)

b) Consider the luteger array AUTO with the lower bound LB= 1932 and opper bound UB = 1984.

In c, the lower bound of our array is always o; it cannot be customized to some other value. Two, to implement a scenario where LB=1932,

we need to use our offset value that logically represent the LB luder value as 1932.

Disadvantages:

y it is relatively expensive to insert and delete elements in an array

is Also, since an array usually occupies a block of memory space, one cannot simply double or triple que size of our array, when additional space is required. (for this reason, argays are called derive lists and are said to be static data structure).

Another way of storing a unt in memory is to have each element in the list contain a field, colled a link or pointer which contains the address of the next Element in

Thus successive elements in the list need not occupy que list. adjacent space in memory.

quis will make it easier to usent a delete elements in the map.

Accordingly, if one were mainly interested in searching through data for inserting and deleting, as in word processing, one should not store the data in array but rather in a list using pointers.

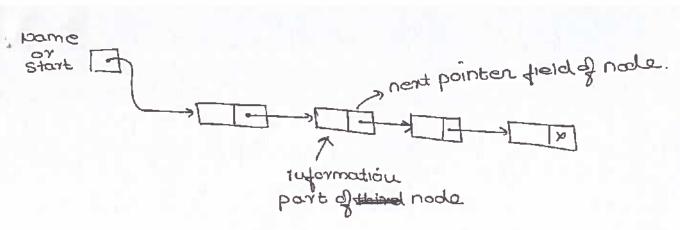

Elis latter type of dota structure is could a luked list and is due main &

Linked bots

of luked lists, or one-waylist, is almean collection of data Elemends, called nodes, where the Linear order is given by means of pointers.

That is, each node is divided that two parts:

qua first part contains que information of due clement, and the second part, called the lik field or next pointer field, contains due address of the nert node in due list.

The null pointer, dentited by x in the diagram,

The linked list also contains a list pointer variable

-called START or Name - which contains the address

of the first node in the list; hence there is an arrow

drawn from START to the first node.

clearly, we need only this address in START to trace

A special case is the list that has no-nodes. Such a list is called the null list or emply list and is denoted. by the null pointer in the variable START.

AVI-Treen

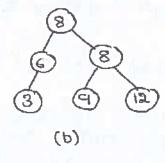

In HB(K), 4 k= 1 (4 bolance factor is one), such a binary Search tree is called an AVI Tree.

That means an AVI tree is a binomy search tree with a balance condition: the dyference between left subtree height and right subtree height is at most I.

Properties of AVL Trees:

A binary tree is said to be an AVI Tree, if:
wit is a binary search tree, and
whor any node x, the height of Left subtree of x and height
of right sobtree of x differ by at most I.

Exi- a is not an AVI Tree. b is a AVI tree.

Minimum/Harimum Number of Nodes in AVI Tree:

of node possible.

If node possible.

That means if we fill the left subtree with height h-1 then we should full the right subtree with height h-2.

As a result, the min-number of nodes with height h is

In the above equation:

. N(h-1) indicates the minimum number of nodes with height h-1.

height h-2.

+ In the above Expression, "I" indicates the current node. We can give N(h-I) either for left subtree or right subtree.

solving the above recurrence given:

Where nio the number of nodes in AVI tree. Also, the above derivation says that the maximum height in AVI trees

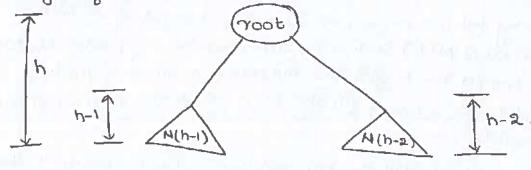

Similarly, to get maximum number of nodes, we need to fill both left and right subtrees with height h-I. As a result,

We get: N(h) = N(h-1)+N(h-1)+1 = 2N(h-1)+1

The above Expression defines the cone of full binary tree. Solving the recurrence we get:

N(h) = O(2h) => h = logn & O(logn).

in both the cases, AVL tree properly is ensuring that the height of an AVL tree with n-nodes is O(logn).

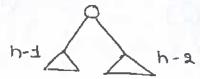

fact: the height of an AVI tree storing 'n' keys is 0 (logn).

Prof: Let us bound n(h): the minimum number of internal nodes of an AVL tree of height h.

- we easily see that n(1)=1 and n(2)=2.
- · for h>2, AVI tree with minimum no of nodes is such that both its subtrees are AVL trees with minimum no of nodes.
- . Such an AVI tree contains the root node, one AVI Subtree of height n-1 and another of height n-2

3hat is, n(h)=1+n(h-1)+n(h-2).

· knowing n(h-1) > n(h-2), we get n(h) > 2n(h-2) Son(h)>2n(h-2), n(h)>4n(h-4), n(h)>8n(n-6)--by induction,

U(H) > 5 (U(H-BT)

choosing i such that h-ai in either tora. we get: n(h) > 2 h/2-1.

Taking logarithms: h < 2 log n(h)+2.

Thus the height of an AVI Tree is O (logn)

Rule to convert from non-AVL to AVL know as AVL-Rotations. 1) Left-Rotations: used when nodes is inserted into right Subtree [of right subtree] ofter inserting new node tree becomes unbalanced.

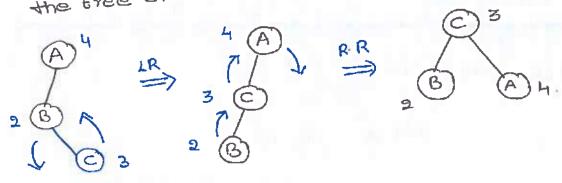

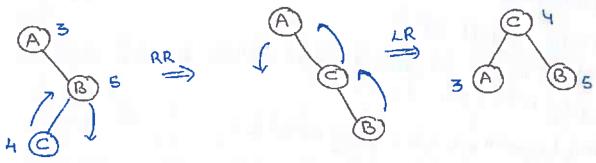

iii) Left-Right Rotation (Double Rotation).

ahio is L(1) type.

in I case we have to solve in two steps, Step 1: Right Rotation and at right child of 'A'

Now Step 2: Left rotation at node A.

why Binary Search Trees?

in we have discussed different tree representations and in all of them we did not impose any restriction on the nodes data. As a result, to search for an Element we need to check both. in left subtree and in right subtree.

Due to this , the worst case complexity of search operation 15 O(n).

Me will discuss another variant of binary trees:

Binary Search Trees (BSTs). As the name suggests, the main use of this representation is for searching. In this representation we impose restriction. on the Kind of data a node can

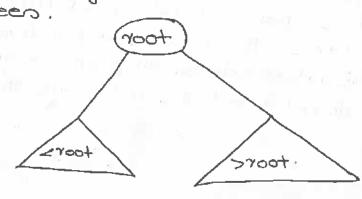

As a result, it reduces the worst case average search contain. operation to o (logn).

Binary search tree property:

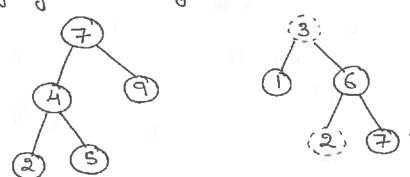

In binary search tree, all the left subtree elements should be less than root data and all the right subtree elements should be greaten than root data.

This is called binary search tree property, note that, this property should be satisfied at every node in the tree.

- . The left subtree of a node contains only nodes with Kerls less the nodes key.
- . The right subtree of a node . contains only nodes with Keys greater than "hodes key.
- · Both the left and right subtrees must also be binary search trees.

Ex: - The left tree is a binary search tree and right tree is not binary search tree . [at node 6 It's not . satisfying the binary search tree property].

Operations on Binary Search trees:

main operations. following are the main operations that are supported by binary search trees.

- v find / find minimum / find maximum element in binary search trees
- v Inserting an element in binary search trees.
- / Deleting our Element from binary search trees.

search tree or not Auriliary operations:

- · finding Kth-smallest element in tree.
- · Sorting the clement of binary search tree and many more

Important Notes on Binary Search Trees:

- · Since root data is always between left subtree data and right subtree data, performing inorder traversal on binary search tree produces a sorted but.
- while solving problems on binary search trees, first we process left subtree, then root data and finally we process right subtree. This means, depending on the problem only the lutermediate step (processing root data) changes and we do not bouch the finot and third steps.

if we are searching for an element and of the 1840 subtree roots data is less than the element use want to search then skip 1t. some in the came with right subtree. Because of this, binary search trees take less time for searching an element than regular

In other words, the binary search trees consider either binary trees. left or right subtrees for searching our element but not poth.

finding an Element in Binary Search Trees.

find operation is straightforward in a BST. Start with the root and keep moving left or right using the BST

If the data we are searching is some an noder then we return current nodes. If the data is not present, we end up in a MULL Link.

Steck.

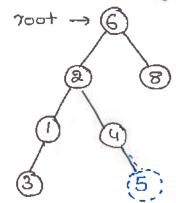

Where is the inorder predecessor and Successor of dustinct?

If X has two children then its inorder predecessor is the maximum value in its left subtree and its inorder successor the minimum value in its right subtree.

if it does not have a left child a node inorder predecessor

Inserting au Element from Hinary Search Irec:

To insert data juto binary Search tree, first we need to find the location for that element, we can find the location of insertion by following the same mechanism on that of find operation.

while finding the location if the data is already there then we

can simply neglect and come out.

Otherwise, Insert data at the last location on the path traversed.

As an Example let us consider the above tree. The dotted node indicates the element (5) to be inserted, To insert 5, traverse the tree as using find fonction. At node with key 4, we need to go right, but there is no subtree, so 6 is not in due tree, and this is the correct location for insertion.

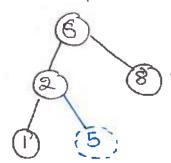

Time complexity: O(n), of in workt cake space complexity: O(n),

Deleting on Element from Binary Search Tree:

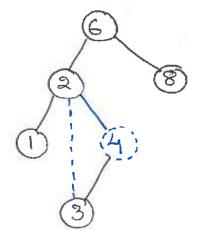

The deleting operation is more complicated than other operations. This is because the clamery to be deleted may not be the leaf node. In this operation also, first we need to find the location of the element which we want to delete.

once we have found the node to be deleted, consider (4)

. If the element to be deleted in a leaf node: return NULL to its parent. That means make the corresponding child pointer NULL. In the tree below to delete 5, set NULL to its parent node 2.

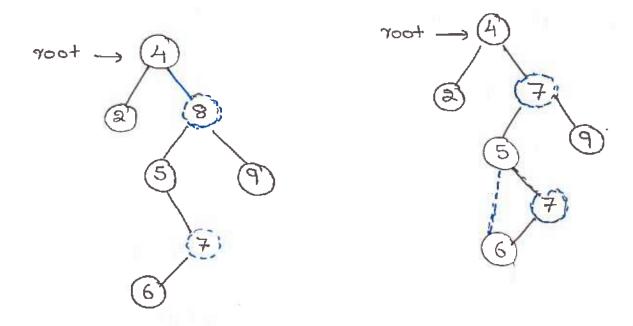

. If the clement to be deleted how one child: In this case we just need to send the correct nodes child to its parent. In the tree below, to delete 4, 4 left subtree is set to its parent node 2.

if the Element to be deleted how both children: The general strategy is to replace the key of this node with the largest element of the left subtree and recursively delete the node (which is now Empty). The largest node in the left subtree cannot have a right child, the second delete is an easy one. As an Example, let us consider the following tree.

In the tree below, to delete &, it in the right onlid of root. The key value is 8. It is replaced with the largest Key in its left Subtree (7), and then that node is deleted as before (second case)

Time complexity: O(1)

Space complexity: O(n) for recursive stack. for Iterative Version, space complexity is 0(1).

Balanced Binary Search Trees:we have seen different trees whose worst come complexity 10 O(n). Where n is the number of nodes in the tree. This happens when the trees are skew trees. In this . Section we will try to reduce this worst case complexity to O(logn) by imposing restrictions on the heights.

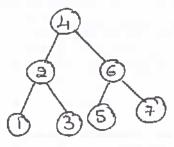

In general, the height balanced trees, one represented with HB(K), where K is the difference between left subtree height and right subtree height. Sometimes K is called poronce factor.

(7)

In HB(K), 4 K= 0 (if Balance factor is zero), then we call such binary search trees.

That means, in HB(0) binary search tree, the difference between tell subtree height and right Subtree height should be at most zero.

This ensures that the tree is a full binony tree

graph is a data structure that consists of following two components:

4) A finite set of vertices also called as nodes. 2. A finite set of ordered pair of the form (u, v) called an edge The pair is ordered because (u, v) is not same as (v, u) in case of directed graph (di-graph). The pair of form (u,v) indicates

that there is an edge from vertex u to vertex v. The edges may contain weight /value/cost.

Graphs are used to represent many real He applications: Graphs are used to represent networks.

The networks may include paths in a city or telephone network

graphs are also used in social networks like linkedin, facebook. for Example, in facebook each person is represented with a vertex (or node). Each node is a structure and contains information like person id, name, gender and locale.

applications of graphs

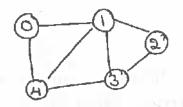

is graphs can be used to model may types of relatious and processes in physical, biological, social and information suptems.

In computer science, graph are used to represent networks of communication, data organization, computational devices,

the flow of computation, etc., for instance, the link structure of a webnite can be represented by a directed graph, in which the vertices represent web pages and directed edges represent links

from one page to another.

following is an Example of undirected graph with 5- vertices

following two are the most commouly used representations. of graph.

1. Adjacency motrix

a. Adjacency list.

3. Edge list [Self-study] There are other representations also like, and incidence matrix and incidence int. The choice of the graph representation in Situation Specific.

It totally depends on the type of operations to performed

and come of time.

Adjacency matrix

Adjacency matrix is a 20 array of size VXV where V is the number of vertices in a graph. Let the 20 array be adj [][], a stot adj [][]]=1 indicates that there is au edge from vertex i to vertex j.

Adjacency matrix for undirected graph is always

Symmetric.

Adjacency matrix is also used to represent weighted duables. if adilignin m' apen aper in an eagle from Vertex i to vertenj. with weight H.

The adjacency modrin for the above Example.

Idea: Travense nodes in layer

Problem: Since we have cycles, each node will be united infinite

Solution: use a boolean visited array

me me doener in imbiementation

Visited: 123456

print : 1, 2, 3, 4, 5, 6

Time complexity: O(V+E)

1: Neufices E: Edges.

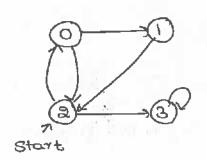

Depth first Traversal or DFS for a graph.

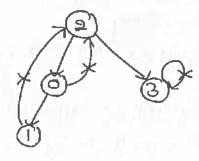

Bepth finst Traversal (or search) for a graph is similar to pepth first Traversal of a tree. The only catch here is, unlike trees, graphs may contain cycles, so we may come to the same node again. To avoid processing a node more than once, we use a boolean VI sited array

for Example:

in the following groth, we start traversal from Vertex 2. when we come to vertex 0, we look for all adjacent vertices of it. 2 is also an adjacent vertex of a. if we don't make vivited vertices, then 2 will be processed again and it will become a non-terminating process

A Depth first traversal of the following graph is

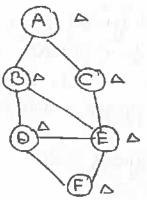

Time complexity: O(V+E) where V is number of vertices in the graph and E is number of edges in the graph.

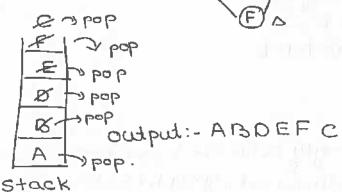

blea: to go forward (indepth) while there is any such possibility, if not then backtrack.

Problem: Since we have cycles, each .

node may be visited infinite times

sol use a boolean visited array.

Time complexity: O(V+E)

129

Depth-first travers on & pplicarion is . Detecting cycle in a graph. & Topological sorting

Let un start our discossion with simple theory that early Introduction: quen on an understanding of the greedy technique in the game of chean,

every time we make a decision about a move, we have to also think about the future consequences,

where an, in the game of Tennin (or Volleyhour), our action in baned on the immediate situation.

Greaty Strategy

Greedy algorithms work in stages. In each stage, a decision is made that is good at that point, without bothering about the future.

This means that some local best in chosen. It assumes that a local good selection maken for a global optimal Solution.

Elements of Grandy Algorithms

The two basic properties of optimal greedy algorithms one:

- 1) Greedy choice properly
- 2) optimal substructure.

Cheegy choice broberth

This properly says that the globally optimal solution (greedy). The obtained by making a locally optimal solution (greedy). The choice made by a greedy algorithm may depend on envilon choicen but not on the fotone. It iteratively maken one greedy choice often another and in reduces the given problem to a smaller one.

optimal substructure

A problem exhibito optimal substructure if an optimal Solution to the problem contains optimal solutions to the Subproblemo.

Tuat means we can solve supproblems a. d build up the solutious to solve larger problems.

Been Greedy Always Gerko?

Haking locally optimal charces does not always coork. Hence, Greedy Algorithma will not always give the best Solution. we will see particular in the problemo.

Advantages and Dusadvantages of Greedy Hethod:

The main advantages of the Greedy method is that it is straight forward, easy of to understand and easy to code. In Greedy algorithms, once we make a decision, we do not have to spend time re-examining the already computed values. Its main disadvantage is that for many problems there is no greedy algorithm. That means, in many cases there is no quarantee that making locally optimal improvements in a locally optimal solution gives the optimal global 801410n.

Greedy Applications

6 sorting selection sort,

b greedy algorithm techniques can be used as an approximation agarithm for complex problems.

Problem 1.

aren an array Fwith size n. Assume the array context. E[1] indicated the remath of the late the and use warms to merge du there files inte oue single file check whether the following algorithm gives the beat solution for this problem or not?

Algorithm: Herge the files contiguously. That means select the first two files and merge them. Then select the output of the previous merge and merge with the third ful, and keep going ..

Note: Given two flies A and B with sizes mound n, the complexity of merglug is a (m+n).

Soi This algorithm will not produce the optimal solution. for a counter example, let us consider the following file sizes array.

F= {10,5,100,50,20,159.

As per dua above algorithm, we need to menge due finot two files (10 and 5 Size files), and as a result we get the following 15 indicates due cost of merging two files with sizes not of files. In the list below,

10 and 5.

§ 15, 100, 50, 20, 15 }.

Similarly, merging 15 with the next file 100 produces: §115,50, 20,15%. for the subsequent steps the hist becomes

£ 165, 20, 154, £ 185, 15 }

¿2003.

The total cost of manging = cost of all manging operations finally, = 15+115+165+185+200 = 680 ·

To see whether due above result is aptimal or not; consider que orden:

\$5,10,15,20,50,100g. for this Example following the same approach, the total cost of merging

- = 18430 + 504100 + 200 = 395
- So, the given algorithm to not giving the bent (optimal)

Hoffman Coding Algorithm [

's It is a lossiers data compression algorithm

Is we assign variable-length codes to input characters, Length of the assigned codes are based on the frequencies of corresponding characters.

The most frequent character gets the smallest code and the Least frequent character gets the largest code.

3 The variable - length coder assigned to input characters are assigned in such a way that the code assigned to one character is not prefix of code assigned to other character.

no ambiguity when decoding the generated bit stream.

blet us understand prefix codes with a counter example.

Let there be four characters a, b, c, and d and their

corresponding variable length codes be 00,01,0 and 1

This coding leads to ambiguity because code assigned to c is prefix of codes assigned to a and b. if the compressed bit stream is oost,

the decompnessed output may be "cccd" or "ccb" or "acd" or "ab".

SApplication of Hoffman coding

Huffman is widely ased in all the mainstream compression formals that you might encounter-from GZIP, PKZIPI winzipetc) and BZIPZ, to Image formals such as JPEG and PNG.

* Broth compression, released by geogle uses
Huffman coding. Apart from that, Broth also uses
LZ77.9 few other fundamental lossiess compression

Elvers are mounty troe major path in Fuffmer coding

- 1) Boild a Hoffman free from input characterus
- 2) Traverse the Hoffman Tree and assign codes to characters.

steps to boild Hoffman tree.

trequency of unique chanacters along with their trequency of occumences and output is Huffman tree.

- heap of all leaf nodes (min heap is used as a priority queueThe volume of frequency field is used to compare two nodes
 in min-heap. Initially, the least frequent character is at
 root)
- 2) Extract two nodes with the minimum frequency from the
- right child. Add this node to the min-heap.
- A) Repeat Steps #2 and #3 until the heat contains only one node. The remaining node to the root node and the tree is complete.

Minimal Spending Tree

The spanning tree of a graph to a subgraph, that contain all the vertices and is also a tree [which has all the Vertices Convered with minimum possible number of edges. Hence, a spanning tree does not have cycles and it cannot be disconnected].

By this definition, we can draw a conclusion that every connected and undirected Graph a has at least one spanning tree.

A disconnected graph does not have any spanning tree, as it cannot be spanned to all its verticies

Example

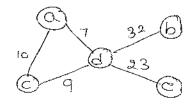

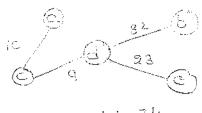

Heighted graphs

weighted graphs in a graph, in which each edge has a weight (some real number).

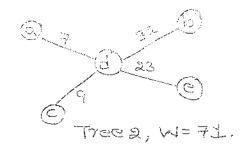

weighted of a graph: The som of the weights of all edges.

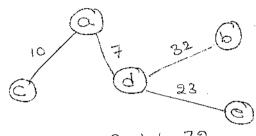

Example:

Tree 1. W= 74

Tree 3, W=72.

Minimum spanning tree.

* A complete undirected graph can have maximum 10^{n-2} number of spanning trees, where n'so the

number of nodes that above addressed example,

General Properties of spanning Tree

one spanning tree following are a few properties of the spanning tree connected to graph G.

was connected graph G can have more than one spanning tree.

- 4 All possible spanning trees of graph G, have the same number of edges and vertices
- is the spanning tree does not have any cycle (Loopal.
- Shemoving one edge from the spanning tree will make the graph disconnected, i.e. the spanning tree is minimally connected.

adding one edge to the spanning tree will create a concain or look to the spanning tree is manifolding adjatic

Application of spanning Tree:

spanning tree to basically used to find a minimum path to connect all nodes in a graph.

common application of spanning trees are.

& Civil network planning

& computer betwork Rooting protocal.

Us cluster Analysis.

Let us & understand this through a small example. Consider City network as a hugh graph and how now plaus to deploy telephone lines in such a way that in minimum lines we can connect to all city nodes this is where the spanning tree comes into picture.

Minimum Spanning-Tree Algorithm

we shall learn about two most important spanning tree algorithms here.

is Prim's algorithm of Both are greedy algorithms.

Fimb Agertin

* If you are use pinary heap and adjacency not the complexity can be of the order of Elogy.

```
quidelines for Asymptotic Analysis
```

There are some general rules to help us determine the running time of an algorithm.

1) Loops: The running time of a loop is, at most, the running time of the statements inside the loop (including tests) multiplied by the number of the Iterations

```
11 Executes n-times .
for (1=1; ik=n; i++)
Total time = a constaud cxn = cn = o(n)
```

2) Nested Loops: Analyze from inside out Total running time to the brogner of the sizes of on the loob is

Mouter loop executed n times. for (1=1; 1 = n; 1+1) } // inner loop executed n-times. for (1=1; 1x=0; 1++) K=K+1; //constaut time .

Total time = Cxnxn = Cn2 = O(n2).

3) Consecutive statements

Add the time complexities of each Statement.

X= X+1; 11 constant time. //executed n-times. for (1= 1; 1= n; 1++).

m=m+a; // constant time l'outer loop executed n-times.

for (1=1; 1=n; 1++) &

11 inner loop executed n-times.

for (1=1; 1=n; 1++)

K= K+1; Il constant time

Total time = co+c1n+c2n2 = O(n2)

```
4) 2-then-else statements:
```

worst-case running time: the test, plus either the then. part or the else part (which ever is the larger).

//test: constaud. if (length () == 0) }

return false; // then past (constant + constant) +1.

for (int n=0; n < Length (); n++) {

//another y: Constaut + constaud (no else part)

if (ilist [U] songo (O4per mot mot [U])) //constaut ·

return table;

Total number: $C_0+C_1+(C_2+C_3)N=O(n)$.

5) Logarithmic complexity an algorithm is O(logn) if it takes a constant time to cut the problem size by a fraction (usually by 1/2)

As an Example Let us consider the following program:

If me observe carefully the value of it is doubling every time initially i=1 in next step i=2, and in subsequent Steps 1= 4,8 and soon.

Let us assume that the loop is executing some K-times At Kth step 2K= D & we come out of Joob

Taking logarithm on both sides, gives

K1095=109U.

K= logn 114 we assume base ~ 2.

Total number = 0 (logn).

```
Problem 1
    what is the complexity of the program given below
     void function ( lut n) {
        lutinik, count=0;
         for (1=1)2; 12=1; 1++)
         for (j=1; j+n/2 <=n; j= j++).
            for (K=1; K=n; K=K+2)
               Count ++;
       3.
    consider the commetts in the following function
      void function (int n) }
          int iiik, count =0;
          11 outer loop executes n-times or n/2.
           for (1=n/2; 1 <= n; 1++)
            // middle loop executes n/2 or n-times.
           tor (j=1; j+n/2 <=n; j=j++)
             louter loop execute logn times.
               for (K= 1; K <= D; K= K+2).
                    count ++
               3.
   The complexity of the above function is o (nº logn)
Problem-2.
      void function (int n) {
         int 1, j, K, count = 0;
          for (i=n/2; ik=n; i++).
             for (3=1; 3=0; ]=2*1)
                for (K=I; K = n; K= K+2).
                   count ++)
        3.
```

```
consider the comments in the following function
          void function (int n) ?
            int i,jik, count=0;
          Il outer loop execute n/2 times.
           for (1=1/2; i=1; i++)
             // middle loop executes logn times
             for (j=1; j <= n; j = 2"j)
                11 outer loop executes logn times
              407 (K=1; K<=n; K=K+2)
                 count ++;
             3.
   The complexity of the above function is O(nlog2n).
Problem-3.
    find the complexity of the program.
       function (Int n) }
           1 (n==1) return;
           for (int i=+; ix=n; i++) }
               for (int j=1; j=n; j++) {.
                   priud + (" + ");
                   break;
    consider the comments in the function below.
        function (lutn) {
            11 constant time.
          if (n==1) return;
          11 outer loop execute n times
          for (int 1=1; 12=1; 1++) }
            Minney loop executes ouly time due to break
            for(int j=1; j <= n; j++) {
                  priut f ("+");
                    break;
       , 33
```

(12)

find the complexity of the recorrence

Sol Let us try solving this function with substitution.

$$T(n) = 2T(n-1) - 1$$

$$= 2(2T(n-2)-1) - 1$$

$$= 2^{2}T(n-2)-2 - 1$$

$$= 2^{2}T(n-2)-2 - 1$$

$$= 2^{2}T(n-2)-2 - 1$$

$$= 2^{3}T(n-3)-2^{2}-2^{1}-1$$

$$= 2^{3}[2T(n-4)-1]-2^{2}-2^{1}-2^{0}$$

$$= 2^{4}T(n-4)-2^{3}-2^{2}-2^{1}-2^{0}$$

$$T(n) = 2^{n} + (n-n) - 2^{n-1} - 2^{n-2} ... + 2^{n-2} + ... + 2^{n-2} - 1$$

$$= 2^{n} - [2^{n} - 1]. \quad [\text{Poote: } 2^{n-1} + 2^{n-2} + ... + 2^{n-2} - 1].$$

$$T(n) = 1$$

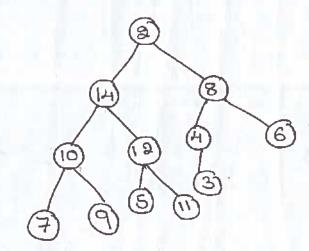

Time complexity is O(1). Note that while the recurrence relation looks exponential the Solution to the recurrence relation here gives a different result.

(3)

is before discussing the method for building heap of our arbitrary complete binary tree, we discuss a simpler problem.

Is let us consider a binary tree in which left and right subtrees of the root satisfy the heap property bud not the root.

What is a tree?

A tree is a data structure similar to a linked list but instead of each node pointing simply to the next node in a linear dashion, each node points to a number of noder.

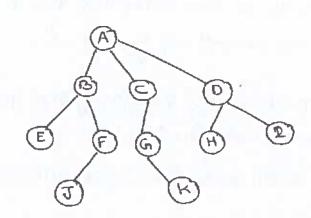

Tree is an Example of a non-linear data structure.

A tree structure is a way of representing the hierarchical nature of a structure in a graphical form.

In trees ADT (Abstract Data Type), the order of the elements is not important.

I we need ordering information linear data structures like linked lists, stacks, queves etc. can be used.

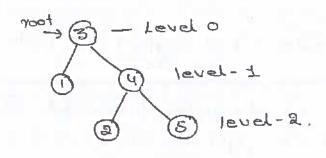

Glossary

- at most one root node in a tree (node A in the above Example)
- An edge refers to the link from parent to child (all links.
- → A node with no-children is called leaf node (E, J, K, H and 2)
 - -> children of same parent are couled biblings (B,C,D are siblings of A, and E,F are the Siblings of B).

- from root to q and p appears on the path.
 - The node q is called a descendant of p for Example.

 A, c and G are the ancestors of K.
- of the tree (B,C and B) are the same level). The root node in at level zero.

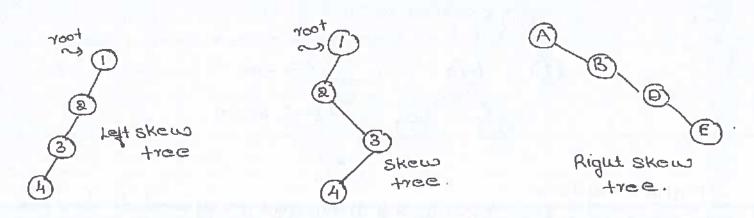

- soot to the node (depth of G is 2, A-C-G).
- node to the deepest node in the Length of the path from that
 - of zero.

Er: the height of B in 2 (B-F-J)

- of Height of the tree in the maximum height among all the order in the tree in the maximum depth of the tree in the maximum.
 - for a given tree, depth and height returns the same value. But for individual nodes we may get different results.
- is It every node has a in a tree has only one child (Except

Aft skew trees

Similarly, if every node has only right child then we call them right skew trees.

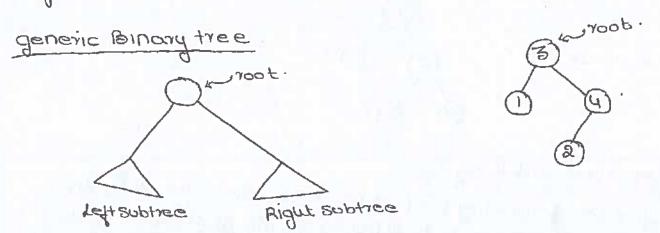

Binary trees

A tree is called binary tree if each node has zero child, one child or two children

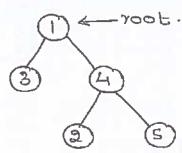

Empty tree is also a valid binary tree.

we can visualize a binary tree as consisting of a root and two disjoint binary trees, called the left and.

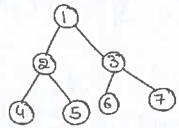

Eype of binary trees:

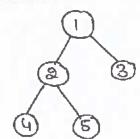

Strict Binary tree is called strict binary tree if each node has exactly two children or no children

Full binary tree: a binary tree is couled full binary tree if each node has exactly two children and all leaf nodes are at the same level

Complete Binary tree

Properties of Binary trees:

for the following properties, let us assume that the height of the tree is h. Also, assume that root node is at height

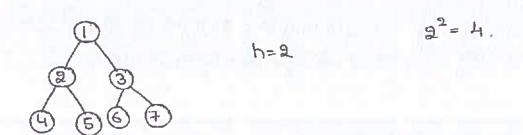

number of nodes at level (5)

2°= 1.

h=1 $2^{1}=2$.

height

h = 0

Since, there are h levels we need to add all nodes at each level.

between 2h (minimum) and 2h+1-1 (maximum)

by the number of Leaf nodes in a full binary is 2h.

Prinary tree of N-nodes is N+ t.

Structure of Binary Trees

Now Let us define structure of the binary tree for

Simplicity, assume that the data of the nodes are

Integers one ways to represent a node (which

contain data) is to have two links which point to left

and right children along with data fields as shown below.

Note: In trees, the default flow is from parent to children and it is not mandatory to show directed branches

for our discussion.

Operations on Binary Trees.

Basic aperations

5 Inserting

& Deleting

is searching

& Traversing

Auxiliary operations

is finding the size of the tree.

6

Glinding the height of the tree

is finding maximum sum.

Applications of Binary trees.

following are the some of the applications where binary

is Expression trees are used in compilers

is Huffman cooling trees that are used in data compression orderestmo.

is Binary search Tree (BST), which supports search, Insertion and deletion on a collection of Itemo in O(logn) [average].

Traversals.

A traversal is a process that visits all the nodes in the tree.

Since a tree is a non-linear data structure, there is no unique travernal

we will consider several traversal algorithms with we group in the following two kinds.

is depth-first traversal is breadth-first traversal

(E)

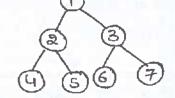

There are three-different types of depth-first traversals: bype order traversal: Visit the parent first of then left and right children.

is In-order traversal: Visit the left child, then the parent.

is post-order traversal: Visit left child, then the right child

Binary tree traversals.

4 preorder traversal. (Root, Left, Right).

- -> Visit the root.
- -> Traverse the left subtree in preorder.
- -> Traverse the right subtree in pre-order.

Ex. 1,2,4,5,3,6,7.

5 In-Order traversal (Left, Root, Right).

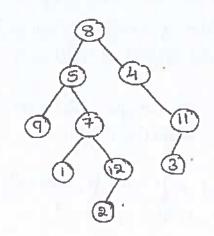

- -) Traverne the left subtree in Inorden
 - -> Visit the root
 - -> Traverse the right subtree in In-order. Ex: 4,2,5,1,6,3,7.

4 Post-order traversal (Left, right, root).

- -> Traverse due left, subtree in post-order.
 - -> Traverse the right subtree in post-order.
 - visit the root.

Er: 4,5,2,6,7,3,4.

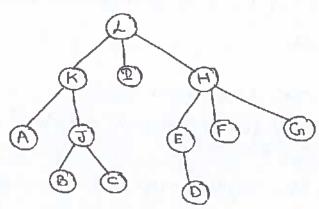

Pre-orden: 8,5,9,7,1,12,2,4,11,3.

Inorden: 9,5,1,7,2,12,8,4,3,11

Postorden: 9,1,2,12,7,5,3,11,4,8

level order: 8,5,4,9,7,11,1,12,3,2.

Problem 2:

Preorden: L, K, A, J, B, C, 2, H, E, D, F, G.

Postorden: A,B,C,J,H,2,D,E,F,G,B,C,D.
A,B,C,J,K,2,D,E,F,G,H,L.

level order/Breadth-first: L,K,I,H,A,J, E,F,G,B,C,D.

She importance of Aldorapmo:

Introduction: The first Step towards an understanding of why the Study and knowledge are so important is to define exactly what we knean by an algorithm.

According to the popular algorithms textbooks:

"introduction to algarithm (second edition by thomas H. cormen, charles E. Leiserson, Ronald L. Rivest, Clifford Etein),

"an algorithm to any well-defined computational procedure that taken some values, or set of values as input and produces some value, or set of values as output".

In-other words, algorithms are like road maps for accomplishing a given, well-defined task.

So, a chunk of code that calculates the terms of the fibonacci. Sequence in an implementation, of a panticular algorithm.

Some algorithms, like those that compute the fibonacci sequences, are intuitive and may be innately embedded into our logical thinking & problem solving skills.

However, for most of us, complex algorithms are best Studied so we can use them as building blocks for more efficient logical problem solving in the future.

In-fact, you may be surprised to learn just how many complex algorithms people use every day when they check their e-mail or listen to music

Here we will introduce some basic ideas related to the analysis of algorithms

Smo qroconcises that chanded the maild!

b Johannes gotenberg: was a german black smith, gold smith, printen, and publisher. who introduced printing to corope.

His introduction of mechanical movable type printing to Europe started the printing revolution.

Decimal System (600 AD)

The decimal number numeral system (also called base to or occasionally denary) has ten as its base. It is the numerical base most widely used by modern civilizations.

Al Khwarizmi (780AD-850AD)

alkhwarizmi contributions to mothematics, geography, astronomy, and cartography established the basis for innovation in algebra and trigonometry. His systematic approach to solving linear and quadratic Equations.

I ed to algebra.

interest on a dought is

Informally, an algorithm is any well-defined compotational procedure that takes some value, or set of values, as cutput.

- we can also view an algorithm as a tool for solving a well-specified computational problem.

Some vocabulary with an Example:

Problem: Sorting of given keys numbers.

Input: A sequence of n-keys, at; ... , an

sequence such that

atealease ... ean .

instance:

An Instance of sorting might be an array of names, likes & mike, Bob, solly... } or a list of number like { 154, 245, 568. }

Algorithm:

An algorithm is a procedure that takes any of the possible input instance and transforms it to the desired output.

Mhich algorithm in better?

Shake one would different orderighms for solvind the broplew

Ex: Sorting

There are three decirable properties for a good alfarithm we seek algorithms that are correct and efficient while being easy to implement.

Measure efficiency (asymptotic notation).

O(n) - Big-O notation

o(n) - Small / Httle - O notation

n(n)-Big-omega notaliou

O(n) - Big-Theta notation

Sorting Algorithmo:

Classification of sorting orderithms

1) Based on data sizes :

s External sort uses primary memory for the data corrently being sorted and secondary storage for any data that will not fit in the primary memory.

5 Internal sort in the sort in which out the data are held in the primary memory during the Sorting process. Based on information about data:

* Comparison based sorting: A comparison based algorithm orders a sorting array by weighing the values of one element against the value of other elements.

Ex:- quick sort, merge, heap, bubbles and insertion sort.

* Nan-comparison based sorting:

an array without consideration of pour wise data elements

Ex: Bucket sort & radin Sort.

* In computer science and mathematics, a sorting algorithm is an algorithm that puls elements of a list in a certain order.

The most-used orders are numerical order and lexicograp-

The output must satisfy two conditions.

+ The output is in non-decreasing order.

* The output is a permutation, or recordering of the

* Randomized Algorithm: is an algorithm that employs a

the algorithm typically uses uniformly random.

The algorithm typically uses uniformly random in the "average case" over all possible choices of random bits.

* Quick sort -> Any deterministic varsion of this

if the algorithm selects pivot Elements uniformly at random, it has a provably high probability of finishing in O(niogn)

Pata Structures:

of several of them.

A data structure is a way to strength of limitations

ond so It is important to know the strength of limitations

ond so It is important to know the strength of limitations

the same word on Ordan transbland goes in a sick topological a gota structure in a slow brodiam can mark

three fundamental obstract data Type

is Containers

& dictionaries & priority queues.

Contiguous ve linked bata structures.

Data structures can be neatly classified as either

Contiguous: contiguous-allocated structures are composed. of single slabs of memory, and include arrays, matrices, heaps, and hash tables.

- Linked data structures are composed of distinct chunks of memory bound together by pointers, and include bests, trees and graph adjacency lists.

dota structura.

Arroy one structures of fixed-size data records such that each element can be efficiently located.

by its Index or (Equivalently) address.

A good analogy likens an array to a street full of houses, "
where each array element is Equivalent to a house,
and the Index is Equivalent to the house number.

Advantages of contiguously-allocated arrays include:

- · Constant time access given the index
- Space efficiench
- · Hemory locality

& Pointers and linked structures.

Pointers are the connections that hold the pieces of linked Structures together.

Pointern represent the address of a location in memory provide more freedom than storing a copy of the item itself.

is stacks & queues:

Container to denote a data structure that permits content.

Container are distinguished by the porticular retrieval

is the two important container

Stacks: Support retrieval by Last-in, first-out (Life)

Stacks are simple to implement and very efficient

one most appropriate for applications (like certain simulations)

and most appropriate for applications (like certain simulations)

There are appropriate for applications (like certain simulations)

Dictionaries:

The dictionary data type permits access to data items. by content. you stick an item into a dictionary so you can find it when you need it.

The primary operations of dictionary support are.

Search (D,K) -

Insert (BIX)-

Delete (Q,x)-

Binary Search trees:

we have seen data structures that allown fast search or flexible update, but not fast search and flexible update ex: unsorted, doubly-linked lists supported insertion and deletion in O(1), but search took linear time in the worst case.

- # Binary search requier that we have fost access to two
 - Specifically the median elements above & below

Algorithm Techniques

& Divide and conquer (D4C)

D2C is an algorithm design passadigm based on multi-branched recursion

A divide and conquer, Algorithm works by recursively breaking down a problem juto two or more sub-problems of the same or related type, until these become simple enough to be solved directly.

to give a solution to the ariginal problem.

Dynamic programming

Bynamic programming (dynamic optimization) is a method for solving a complex problem by breaking it down tuto a collection of simplex sub problems, solving each of those subproblems funt once, & staring their solution-theaty, using a memory-based data structure.

recomputing its Solution, one simply looks up the previously computed solution, there by soving computation time at the Expense of a modest Expenditure in storage space.

Optimization.

to give the best solution for given problem. Examine the

42n companison - greedy algorithm.

Matrix chain product:

Example of dyamic programming

given a sequence of modrices, find the most efficient way to multiply these modrices together. The problem is not actually to perform the multiplications, but merely to decide in which order to perform the multiplications.

greedy Approach.

Greedy Algorithm is an algorithm poradigm that follows the problem solving heuristic of making the locally optimal choice at each stage with the hope of finding global optimum.

In many problem, a greedy strategy doesnot in general produce an optimal solution Ex: Travel schesman problem

Krusol's minimum spanning tree Algorithms.

what is a stack?

A stack is a simple data structure used for storing data (Similar to linked lists). In a stack, the order in which the data arrives is important.

Apile of plates in a cofeteria is a good example of a stack. The plates are added to the stack as they one cleaned and they are placed on the top.

when a plate, is required it is taken from the top of the stack.

The first placed on the stack is the Last one to be used.

Definition:-

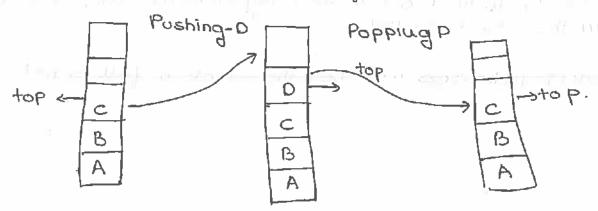

a stack in an ordered list in which insertion and deletion are done at one end, called top. The dast element inserted in the first one to be deleted. Hence, it is called the last in first out (LIFO) or first in Last out (FILO) list.

Special names are given to the two changes that can be made to a stack.

when an element in Inserted In a stack, the concept in called push, and when an element is removed from the Stack, the concept is called pop.

Trying to pop out an Empty stack is called underflow and trying to push an element in a full stack is Called Overflow

Generally, we treat them as exceptions. As an example, consider the snapshoto of the stack.

How stacks are used.

consider a working day in the office. Let up assume a developer is working on a long-term project. The manager then gives the developer a new task which is more important.

The developer puto the lang-term project aside and begins work on the new tack. The phone rings, and this is the highest priority as it must be answered immediately.

The developer pushes the present task into the pending

When the call is complete the bask that was abandoned to answer the phone is retrieved from the pending tray and work progresses. To take another call, it may have to be handled in the Same manner, but eventually the new task will be finished, and the developer can draw the long-term project from the pending tray and continue with that.

STACK ADT

The following operations make a stack an ADT. for simplicity, assume the data is an integer type.

Main Stack operations

to push (int data): Inserto data outo stack.

In int Pop (): Removes and returns the Last inserted element from the Stack.

Aurillary stack operations

s tut Top (): Returns the Last inserted element without removing it.

Int size(): Returns the number of elements stored in the stack.

Int Is Empty stack(): Indicated whether any elements are stored in the Stack or not.

Int is full stack (): Indicates whether the stack is full or not

Attempting the execution of an operation may sometimes cause an error condition, called an exception. Exceptions are said to be "thrown" by an operation that cannot be executed. In the stack ADT, operations pop and top cannot be performed if the stack is Empty.

Attempting the execution of pop (top) on an empty stack

Trying to push an Element in a full stock thrown our exception.

Applications

following are some of the applications in which stacks play an important role.

Direct Applications

6 Balancing of symbols.

5 Infix-to-post fix conversion.

is Engliation of bostfix expression

is implementing function calls (including recursion)

& finding of spans (finding spans in stock markets), refer to Problems section).

is page-Visited history in a web browsen [Back Buttonn] is undo-Sequence in a text editon.
Is matching Tago in HTML and XML.

Indirect applications

& Auxiliary data structure for other algorithms. [Ex: Tree

6 component of other data structures (Ex: Simulating queues, refer Queues chapter)

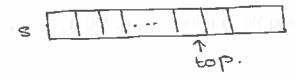

Implementation

There are many ways of Implementing Stack ADT; below are the commonly used methods.

is simple array based implementation.
Is Dynamic array based implementation.
Is Linked lists implementation.

Simple Array Implementation

The implementation of stack ADT uses an array. In the array we add elements from Left to right and use a variable to keep track of the index of the top element

The array storing the stack elements may become full. A push operation will then throw a full stack exception Similarly, if we try deleting an element from an emply stack it will throw stack empty exception.

Performance 2 limitations

what is a queue?

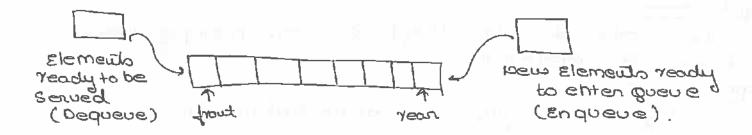

Aqueve is a data structure used for storing data (similar to Linked lists and stacks). In queue, the order in which data arrives usuling to be served in sequential order starting at the beginning of the line or sequence.

Belinition:-

done at one end (rear) and deletious are done at other end (front). The first element to be inserted is the first one to be deleted. Hence, it is called first in first out (FIFO) or last in last out (LILO) list.

Similar to stacks, special names are given to the two changes that can be made to a queve. when an element is inserted in a queve, the concept is called Engueve, and when an element is removed from the queve, the concept is called Dequeve

Degreeing an Empty queve in couled underflow and Enqueving an Element in a full queve in couled overflow Generally, we treat them an exceptions. As an Example, consider the snapshot of the queve.

How are brener med;

of the line in the one who will be served next. He will at a reservation counter. when we enter the line we stand at a reservation counter. when we explained by observing a time. But the concept of a queue can be explained by observing a time.

Queue ADT

The following operations make a queue an ADT. Insertions and deletions in the queue must follow the FIFO Scheme. for simplicity we assume the elements one integers.

Main Queue operations

& Enqueue (Int data): Inserts an element at the element at the front of the queue.

Awxiliary goeve operations

Intfrout (): Return to the element at the front without removing

jut greve size(): Returns the number of elements stored in the

fut is smpty gueve i): Indicates whether no elements are stored in

Exceptions

Similar to other ADTD, executing be governed on an Empty queve throws an "Empty queve exception" and executing Engueve on a full queve throws "full queve exception".

Applications

Similar to other ADTO, Executing De gueve on an empty queve

Applications

following are some of the applications that me drener

Direct applications.

- order of arrival (e.g. a print queve).
- & simulation of real-world queves such as lines at a ticket counter or any other first-come first-served scenario requires a queve.

Pholpibachammind

la Asynchronous data transfer (file 20, pipes, sockets)

& waiting times of customers at call center.

is peterming number of cashiers to have at a supermarket.

Indirect Applications

6 Auriliary data structure for algorithms to companient of other data structures.

Imblemengation:

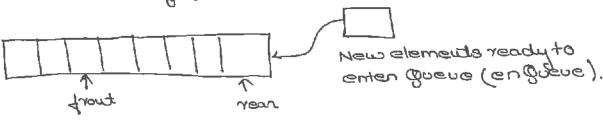

There are many ways (similar to stacks) of implementing queve operations and some of the commonty used methods are listed below

is simple circular orray based implementation. is pyramic circular array based implementation & Linked list implementation.

Why circular Arrays

first, let us see whether we can use simple arrays for implementing quever as we have done for stacks. We Know that, in queues, the innertious are performed at one end and deletious are performed at the other end. After performing some insertions and deletions the process becomes easy to understand.

In the Example shown below, It can be seen clearly that the initial slots of the array are getting wanted. So simple array implementation for queve is not efficient. To solve ties problem we assume the arrays as ancular arrays. That means, we treat the Last element and the first arrang elements as contiguous with this representation, 4 there are any tree sloto at the beginning, the rear pointer can easily go to 1 to next free alots.

0.000

The first and the second of th
